UKM Geophysics: Past, present and future

Mohd Hariri Arifin

Date: 14 December 2022

Platform: Microsoft Teams

The field of geophysics is one of the main sub-fields under the Geology program, Universiti Kebangsaan Malaysia (UKM). Since UKM was established in 1970, undergraduate level geophysics has been taught by Dr. Ismail Mohd Noor and several contract lecturers from renowned Indonesian universities. This geophysics course was then taught by Dr. Abdul Rahim Samsudin who is a geology graduate from UKM who successfully obtained a Master of Science (Geophysics) degree from the University of Leeds United Kingdom in 1975. Also joining forces to teach this geophysics course is Dr. Umar Hamzah who obtained a Master's degree in Science (Geophysics) from the University of Birmingham (UK). Now the legacy is continued by Dr. Mohd Hariri Arifin and other academic colleagues in the geology program. The pairing of academic staff for this course has yet to be filled as there are no candidates with suitable qualifications based on the university's current requirements. At the undergraduate level, the engineering and environmental geophysics program has been introduced as coursework since 2010. This geophysics master's program is more focused on exploration and applied aspects and focuses heavily on the four main geophysical methods, namely the geoelectrical resistivity method, the seismic method, and the gravity and magnetic method. The use of geophysical methods in various fields, especially engineering and the environment, including the exploration of earth resources, underground water (cold/hot/saltwater intrusion), pollution (landfills and oil spills), archaeology, site investigation (development and engineering problems) and meteorites impacts. In the future, UKM geophysics is determined to continue contributing especially in the development of geothermal resources and the exploration of rare earth resources.

Geological aspects in earthquake engineering

Azlan bin Adnan

Date: 11 January 2023

Platform: Microsoft Teams

Geological aspects play important roles in determining seismic hazard of a region. Seismic hazard in Malaysia is associated with the geological conditions of faults movement and seismicity originating from seismically active faults in neighboring countries such as Indonesia and Philippines. Being situated on the stable Sunda plate, most people perceive that Malaysia is free from the life-threatening seismic crisis. The Malaysian Network of Seismological Stations have been recording distant ground motions from the two most active plate tectonic margins in the world, which are the 1650 km long Sumatran fault and the Philippines plate. In addition, several earthquakes due to local active faults with the maximum moment magnitude of 4.4 have also been observed within Peninsular Malaysia since 2007. Even though the local earthquakes were small, the epicenters were as close as 20 km to Kuala Lumpur, which a slightly higher value of magnitude could have remarkable effects on seismic hazard of the region. The big earthquake of 6.0 Magnitude occurred on 5th June 2015 at a depth of approximately 10 km, with its epicentre
